Data and Results

Conclusions:

- Medical students experienced more symptoms of depression directly before exams compared to directly after exams. This was significant for all symptoms of major depressive disorder (MDD) except for psychomotor agitation or retardation and suicidal ideation.

- Both before and after exams, female medical students experienced symptoms of MDD at overall greater rates compared to male medical students.

- Both male and female medical students experience symptoms of depression at high rates both directly before and after exams.

- This study shows the importance of understanding how medical school exams impact students’ mental health, and supports further research on the topic to better find ways to improve the mental health of our future health care leaders.

Background

Research shows that medical students experience high rates of depressive symptoms throughout their training, with female medical students often found to have higher rates of depression compared to their male counterparts. In addition, high levels of performance-based self-esteem, and depressive symptoms in medical students have been linked to increased risk of being diagnosed with a psychiatric illness such as MDD later in training. However, there is limited research on major depressive disorder (MDD) symptoms experienced by medical students directly surrounding medical school examinations. Previous research from our group suggests that female medical students experience more symptoms of depression after exams compared to male medical students. However, in the previous study symptoms were measured only directly after exams.

Aim:

In the present study, we aimed to look at symptoms of major depressive disorder in first-year and second-year medical students three days before and three days after medical school exams to better characterize the effects of exams on students’ mental health.

Hypothesis

1. Female medical students will have more symptoms of depression both before and after medical school exams
2. Medical students will experience symptoms of MDD both directly before and after medical school exams while experiencing more symptoms after exams

Methods:

An anonymous and secure survey was sent via University email to first- and second-year medical students on the day of medical school exams, and students were asked about symptoms of MDD as defined by the DSM-V for the three days leading up to the exam. A second survey was sent out three days after the exam to ask about the same symptoms in the three days since the exam.
